## Perturbation of the first and second orders

a) $1^{\text {st }}$ order: degenerate AOs

E

b) $2^{\text {d }}$ order: AOs of different energies

Bonding orbital

## The rules of QMOT

1. Consider valence $A O$ only (e.g., for Carbon, (N, O, F) $2 \mathrm{~s}, 2 \mathrm{px}, 2 \mathrm{py}$ and 2 pz )
2. Form MOs for entire system as linear combination of AOs. Remember, combination of

N AOs gives N MOs (same as for hybrid orbitals)
3. MOs must be either symmetric or antisymmetric with respect to the symmetry operations of the molecule.

For example, $\mathrm{H}_{3}{ }^{+}$- ptotonated $\mathrm{H}_{2}$ molecule of $\mathrm{C}_{2} \mathrm{v}\left(\mathrm{D}_{3 \mathrm{~h}}\right.$ ?) symmetry

Neither symmetric no asymmetric
$\mathrm{H}_{3}{ }^{+}$- the simplest polyatomic molecule and the most abundant ion in the Universe

## Experimentally- triangular structure, $\mathrm{H}-\mathrm{H}$ distance is $1 \AA$.

The protonation energy of $\mathrm{H}_{2}$ is surprisingly large:
$\mathrm{H}_{2}+\mathrm{H}^{+} \rightarrow \mathrm{H}^{+} \Delta \mathrm{H}=-100 \mathrm{kcal} / \mathrm{mol}$

$$
\mathrm{H}+\mathrm{H} \rightarrow \mathrm{H}_{2} \quad \Delta \mathrm{H}=-103 \mathrm{kcal} / \mathrm{mol}
$$

Delocalization of 2 electrons over 3 centers

4. Compose MOs for structures of higher symmetry and then produce MOs for related but less symmetric systems by systematic distortion of the MOs of higher symmetry. For example, for the $\mathrm{CH}_{2}$ system, start with linear HCH $\left(D_{\infty h}\right)$ then bend the system $\left(C_{2 v}\right)$.
5. Molecules with similar structures, such as $\mathrm{BH}_{3}, \mathrm{CH}_{3}{ }^{+}, \mathrm{CH}_{3}, \mathrm{CH}_{3}^{-}, \mathrm{NH}_{3}$, $\mathrm{OH}_{3}{ }^{+}$, have qualitatively similar MOs , the major difference is the number of electrons that occupy the common MO system. Firstly build MOs, then occupy them with valence electrons
6. The total energy of the system is a sum of the energies of occupied MOs.
7. If the two highest energy MOs of a given symmetry were derived primarily from the different kinds of AOs (s and $p$ ), then mix the two MOs to form hybrid orbitals. For example, for the AH2 system (p.3), mix C and E orbitals to form hybrids C' and E'.

8. a) The smaller the initial energy gap between 2 interacting orbitals, the stronger the mixing.
b) The energy of stabilization, $\mathrm{E}_{\text {stab }}$, is always smaller than energy of destabilization, $\mathrm{E}_{\text {destab }}$. Thus, 4 electron-2center, $4 \mathrm{e}-2 \mathrm{c}$, interaction is always repulsive, $3 \mathrm{e}-2 \mathrm{c}$ is weakly bonding, $2 \mathrm{e}-2 \mathrm{c}$ is bonding.
c) If orbitals of different energies interact (b), the one of lower energy, B, will contribute more in binding orbital; the one of higher energy, A, will contribute more in antibonding orbital.
d) The more electronegative atoms have lower energy (more negative) AOs

|  | H | B | C | N | O | F | Cl |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Electroneg | 2.1 | 2.0 | 2.5 | 3.0 | 3.5 | 4.0 | 3.0 |
| IE,eV | 13.6 | 8.3 | 11.3 | 14.5 | 13.6 | 17.4 | 13.0 |

e) The larger the overlap between interacting orbitals, the larger the interaction. $\sigma$-bonds are stronger than $\pi$-bonds.

Using QMOT for prediction of geometries and ground electronic states of small systems: $\mathrm{AH}_{2}, \mathrm{AH}_{3}$, and $\mathrm{AH}_{4}$, where A is a second period element.

$$
A H_{2}: A=B, C . N, O
$$

1. Is $A H_{2}$ system linear ( $\mathrm{D}_{\text {oh }}$ ) or bent $\left(\mathrm{C}_{2 \mathrm{v}}\right)$ ?
2. Is it closed-shell singlet or triplet? If it is radical (one unpaired electron) is it bent or linear?
3. Build MOs for the system of highest symmetry- $D_{\infty h}$. Then bend it to $C_{2 v}$. Upon the bending, the overlap between AOs in MOs will change. Thus, some MOs will go up in energy some down. The change in total energy of the system could be predicted.
4. Place the system in the Cartesians ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ) and DO NOT change the orientation!

# 2e- bent $\left(\mathrm{H}_{3}{ }^{+}\right)$ <br> 3,4e-linear $\left(\mathrm{BeH}_{2}, \mathrm{BeH}_{2}{ }^{+}\right)$ <br> 6,7 e-bent $\left(\mathrm{CH}_{2}, \mathrm{NH}_{2}, \mathrm{NH}_{2}{ }^{+}\right)$ 

8e-bent $\left(\mathrm{OH}_{2}, \mathrm{H}_{2} \mathrm{~F}^{+}\right)$

The most dramatic change: nonbonding orbital to bonding

Depending on the electronegativity of the central atom:
The smaller the electronegativity- the higher the p-orbitals-the smaller the gap between bonding and antibonding orbitals (often HOMO-LUMO) - the stronger the mixing- the more favorable the bent structure, i.e., the smaller the bond angle

More electronegative central atom

## electronegativity

|  | $\mathrm{H}_{2} \mathrm{Te}$ | $\mathrm{H}_{2} \mathrm{Se}$ | $\mathrm{H}_{2} \mathrm{~S}$ | $\mathrm{H}_{2} \mathrm{~N}^{-}$ | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{H}_{2} \mathrm{~F}^{+}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| HAH angle | 90.3 | 90.6 | 92 | 104 | 104.5 | 118.1 |

Photoelectron spectrum of water

Find 2 lone pairs

We could apply the same Walsh diagram for substituted compounds, say for $\mathrm{NF}_{3}$
Halogen atoms are considered as one-valence electron substituents, similar to H but with p-orbital instead of s

Influence of substituents:
Electronegative substituents stabilize the pyramidal form compared to planar.

Substituents do not affect the nonbonding D orbital of the planar form but they certainly "pull down" D' MO of the pyramidal form since the pAO of the electronegative atoms are lower in energy than s-AO of H .
$\Delta \mathrm{H}, \mathrm{kcal} / \mathrm{mol}$

## Degenerate inversion of $\mathrm{NH}_{3}$

The reaction barrier to inversion is low- the process is very fast.
For $\mathrm{NF}_{3}$ the barrier is much higher- $\mathrm{ca} .80 \mathrm{kcal} / \mathrm{mol}$
For $\mathrm{PH}_{3}$ the barrier is significantly higher than for $\mathrm{NH}_{3}-\mathrm{ca} .35 \mathrm{kcal} / \mathrm{mol}$

Walsh diagram for the $\mathrm{AH}_{4}$ system (Td to $\mathrm{D}_{4 \mathrm{~h}}$ )

MOs of $\mathrm{CH}_{3}$ are consistent with its PER spectrum, hybrid orbitals are not

Problem of planar tetracoordinated carbon.

Is it possible to make a structure with planar carbon?

Making MOs of complicated systems using MOs of simple systems as fragments
$\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2} .12 \mathrm{e}$

MOs of $\mathrm{H}_{2} \mathrm{C}=\mathrm{O}$. It is isoelectronic to ethylene- MOs are the same, perturbed by O atom

## Orbital "tilting"

The direction of nucleophilic attack is not perpendicular to the plane but rather to by ca. $105^{\circ}$ (the Bürgi-Dunitz angle).
