# CONSTRAINT PROCESSING AND HEURISTIC SEARCH

LECTURE 19 – SELECTIVE SEARCH (CONT'D)

Dr. Jean-Alexis Delamer

## Recap

- Some problems **can't be solved optimally**.
  - But we can find an **approximate solution**.
- **Local search**:
  - Consider a **local neighborhood**.
  - Try to find a **global optimum**.
  - But we can be **stuck in local optimum**.
- Some algorithms try to reduce this downside.
  - **Hill-Climbing**
  - **Simulated Annealing**

# Genetic Algorithms

- Local search techniques are still **regular search algorithms**.
  - Define **successors of a state** (neighborhood) differently.
  - Use **randomization to avoid local optimum**.
- Researchers tried to find other methods to solve hard problems.
  - A very popular method is **genetic algorithms**.
  - Only an introduction.

## History of GAs

- As early as 1962, John Holland's work on **adaptive systems** laid the foundation for later developments.
- By the 1975, the publication of the book *Adaptation in Natural and Artificial Systems*, by Holland and his students and colleagues.

## History of GAs

- Early to mid-1980s, **genetic algorithms** were being applied to a broad range of subjects.
- In 1992 John Koza has used genetic algorithm to **evolve programs to perform certain tasks**. He called his method "**genetic programming**" (GP).

# Genetic Algorithms

- What is a genetic algorithm?
  - A genetic algorithm (or GA) is a search technique used to find **true or approximate solutions** to **optimization and search problems**.
  - They **are global search heuristics**.
  - They are a class of **evolutionary algorithms** that use techniques inspired by evolutionary biology such as **inheritance, mutation, selection, and crossover (also called recombination)**.

# Genetic Algorithms

- How does it work?
  - The evolution usually starts from a **population** of **randomly generated individuals** and **happens in generations**.
  - In each generation, the **fitness** of every individual in the population is evaluated, multiple individuals are **selected** from the current population (based on their fitness) and **modified** to form a new population.
  - The new population is **used in the next iteration**.
  - Terminates when either a **maximum number of generations has been produced**, or a **satisfactory fitness level has been reached** for the population.

## Genetic Algorithms

- Terminates when either a **maximum number of generations has been produced**, or a **satisfactory fitness level has been reached** for the population.
- **Why?**
  - No convergence rule or guarantee.
  - The number of generations to make sure it terminates.

# Genetic Algorithms

- We need to define some terms first.
  - **Individual**: Any possible solutions.
  - **Population**: Group of all individuals.
  - **Fitness**: Target function that we are optimizing, our  $f$ -value.
  - **Trait**: Possible aspect (features) of an individual.
  - **Genome**: Collection of all chromosomes (traits) for an individual.

# Genetic Algorithms

- **Basic Genetic Algorithm:**
  - Start with a large “**population**” **randomly generated**.
    - Each **individual** is a potential solution to a problem
  - Repeatedly do the following:
    - Evaluate each individual.
    - **Probabilistically** keep a subset of the best solutions.
    - Use these solutions to generate a new population.
  - Stop when you reach a terminate condition (good solution or number of generation).

# Genetic Algorithms

- **Example MaxOne problem:**
  - Suppose we want to **maximize the number of ones** in a string of  $n$  binary digits.
  - An individual is encoded as a string of  $n$  binary digits.
  - The fitness  $f$  of a candidate solution to the MaxOne **problem is the number of ones** in its genetic code.
  - We start with a population of  $k$  random strings (individuals).

# Genetic Algorithms

- **Example:**
  - We suppose that  $n = 10$  and  $k = 6$ .
  - We generate a first population:

$$s_1 = 1111010101 \quad f(s_1) = 7$$

$$s_2 = 0111000101 \quad f(s_2) = 5$$

$$s_3 = 1110110101 \quad f(s_3) = 7$$

$$s_4 = 0100010011 \quad f(s_4) = 4$$

$$s_5 = 1110111101 \quad f(s_5) = 8$$

$$s_6 = 0100110000 \quad f(s_6) = 3$$

# Genetic Algorithms

- **Step 1: Selection**

- We randomly (using a biased coin) select a subset of the individuals based on their fitness:
  - Individual  $i$  will have a probability to be chosen  $\frac{f(i)}{\sum_i f(i)}$

$$s_1 = 1111010101 \quad f(s_1) = 7$$

$$s_2 = 0111000101 \quad f(s_2) = 5$$

$$s_3 = 1110110101 \quad f(s_3) = 7$$

$$s_4 = 0100010011 \quad f(s_4) = 4$$

$$s_5 = 1110111101 \quad f(s_5) = 8$$

$$s_6 = 0100110000 \quad f(s_6) = 3$$

# Genetic Algorithms

- Example:
  - Suppose that after performing we get the following:

$s_1 = 1111010101$	$f(s_1) = 7$	$\longrightarrow$	$s'_1 = 1111010101$	$(s_1)$
$s_2 = 0111000101$	$f(s_2) = 5$	$\longrightarrow$	$s'_2 = 1110110101$	$(s_3)$
$s_3 = 1110110101$	$f(s_3) = 7$	$\longrightarrow$	$s'_3 = 1110111101$	$(s_5)$
$s_4 = 0100010011$	$f(s_4) = 4$	$\longrightarrow$	$s'_4 = 0111000101$	$(s_2)$
$s_5 = 1110111101$	$f(s_5) = 8$	$\longrightarrow$	$s'_5 = 1110111101$	$(s_4)$
$s_6 = 0100110000$	$f(s_6) = 3$	$\longrightarrow$	$s'_6 = 1110111101$	$(s_5)$

# Genetic Algorithms

- **Step 2: Crossover**

- Next, we mate strings for crossover.
  - For each couple we first decide (using some pre-defined probability, for instance 0.6) whether to perform the crossover or not.
  - If we decide to perform crossover, we randomly extract the crossover points.

- Before crossover:

- After crossover:

$$s'_1 = 1111010101 \quad s'_2 = 1110110101$$

$$s'_1 = 1110110101 \quad s'_2 = 1111010101$$

# Genetic Algorithms

- **Step 3: Mutations**

- The final step is to **apply random mutations**: for each bit that we are to copy to the new population we allow a **small probability of error** (for instance 0.1).

Initial strings		After mutating
$s''_1 = 1110110101$		$s''_1 = 1110100101$
$s''_2 = 1111010101$		$s''_2 = 1111110100$
$s''_3 = 1110111101$	→	$s''_3 = 1110101111$
$s''_4 = 0111000101$		$s''_4 = 0111000101$
$s''_5 = 0100011101$		$s''_5 = 0100011101$
$s''_6 = 1110110011$		$s''_6 = 1110110001$

# Genetic Algorithms

- Then we iterate.
  - In one generation, the total population fitness changed from 34 to 37.
  - An improvement of 9%.
- At this point, we go through the same process all over again, until a stopping criterion is met.

# Genetic Algorithms

- Example *n*-queens.

## Initial population

24748552	24	31%
32752411	23	29%
24415124	20	26%
32543213	11	14%

## Selection

32752411
24748552
32752411
24415124

## Cross-Over

32748552
24752411
32752124
24415411

## Mutation

32748152
24752411
32252124
24415417

## Fitness Function

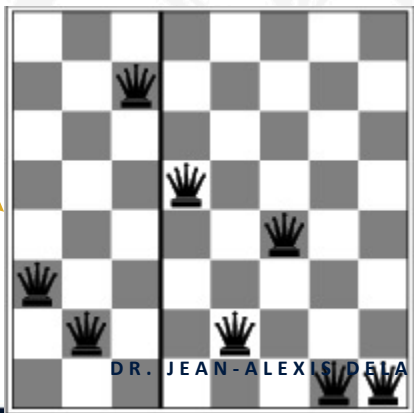

**Fitness function:** number of **non-attacking** pairs of queens  
(min = 0, max =  $8 \times 7/2 = 28$ . The higher the better)

$$24 / (24 + 23 + 20 + 11) = 31\%$$

$$23 / (24 + 23 + 20 + 11) = 29\% \text{ etc}$$

probability of a given pair selection  
proportional to the fitness (b)

Random mutation

# Genetic Algorithms

# Genetic Algorithms

- Common representation methods:
  - Binary strings.
  - Arrays of integers (usually bound).
    - Why?
  - Arrays of letters.
  - Etc.

# Genetic Algorithms

- **Methods of selection.**
- There are many different strategies to select the individuals to be copied over into the next generation:
  - Roulette-wheel selection.
  - Elitist selection.
  - Fitness-proportionate selection.
  - Scaling selection.
  - Rank selection.

# Genetic Algorithms

- **Roulette wheel selection.**
  - Conceptually, this can be represented as a game of roulette.
  - Each individual gets a slice of the wheel.
  - But more fit ones get larger slices than less fit ones.

Done in the examples.

# Genetic Algorithms

- **Elitist selection:**
  - Chose only the most fit members of each generation.
- **Cut-off selection:**
  - Select only those that are above a certain cut-off for the target function.

# Genetic Algorithms

- Methods of reproduction:
  - There are primary methods:
    - Crossover
    - Mutation
  - Crossover:
    - Two parents produce two offspring
    - Two options:
      1. The chromosomes of the two parents are copied to the next generation
      2. The two parents are randomly recombined (crossed-over) to form new offsprings.
  - In the example we used option 2.

# Genetic Algorithms

- Other crossover strategies:
  - Randomly select a single point for a crossover
  - Multi point crossover
  - Uniform crossover

# Genetic Algorithms

- Uniform crossover:
  - A **random subset** is chosen
  - The subset is taken from parent 1 and the other bits from parent 2.

Subset: BAABBAAB generated randomly

# Genetic Algorithms

- Mutations:
  - Generating new offspring from single parent.
  - Append with a small probability.

# Genetic Algorithms

- **Exercise:**
  - Propose a Genetic algorithm for the Traveling Salesman Problem.
    - State representation.
    - Crossover method.
    - Mutation method.

# Genetic Algorithm

- Representation:
  - An ordered list of city numbers.
  - Known as an **order-based** GA.
- Examples:
  - 1) London, 2) Venice, 3) Moscow, 4) Singapore, 5) Beijing, 6) Phoenix, 7) Tokyo, 8) Ottawa
  - You can generate a population:
    - CityList1 (3 5 7 2 1 6 4 8)
    - CityList2 (2 5 7 6 8 1 3 4)

# Genetic Algorithm

- Crossover:
  - We can use inversion and recombination.

This operator is called the Order1 crossover

# Genetic Algorithms

- Mutation:
  - We partially reorder the list.

# TSP Example: 30 Cities

# TSP Example: 30 Cities

TSP30 (Performance = 941)

# TSP Example: 30 Cities

TSP30 (Performance = 800)

# TSP Example: 30 Cities

TSP30 (Performance = 652)

# TSP Example: 30 Cities

TSP30 Solution (Performance = 420)

# Genetic Algorithms

- Concept is easy to understand.
- Always an answer.
- Flexible building blocks for hybrid applications
  
- As often with heuristic search, it requires expert knowledge to design a good genetic algorithm.
  - State representation.
  - Crossover method.
  - Mutation method.
